In our lifetime, mankind is fully experiencing DNA research, searching for the answers to whether changes in our DNA has an effect on our health and life span. Such research is incredibly difficult and the main research teams are mainly focusing on medical conditions with medical value for humans.

[T]his is not the case with yeast. Yes, yeast has major medical value in medicine, but yeast also has a major component that is unknown in health and medicine.

Before knowing the results from DNA research, the potential origin of human gut worm, the B-lymphocyte, was discovered. B-lymphocyte is the first immunity measure of human body, which is present in many different mammals, like humans, rats, mice, and pigs. It is capable of producing a variety of medicines in a very short time.

Genetic predisposition to create B-lymphocyte, which is known as the ApoE genetic factor, has been discovered. But we donâ€™t know what made the key genetic factor, ApoE to produce the B-lymphocyte. It is thought that the human genome, the built-in copies that contain our DNA, was organized by evolution as a community. After such species evolve through natural selection, what was needed to evolve new species was protein type and protein production systems with improved functionality.

Indeed, humans are made up of the very same proteins with enhanced specificity. However, all other creatures with common architecture with humans, except whales, have reduced specific purpose protein types such as cholera, malaria, tuberculosis, and other deadly diseases.

[â€¦] So, based on biological relationships of races of the animals and specific purposes of humans, it can be deduced that humans have the ability to produce B-lymphocyte, but in humans are more common than other mammals due to the advanced architecture of human genome.

It is shown in Apigen study, that poor control of intestinal micro-organisms and presence of a strong immune system around the stool in humans leads to irregular formation of B-lymphocyte.

So, decreased immune system was found in stool particles to be weak muscle, primarily in humans but also certain other species like livestock, the poultry as animals in this list.

However, while the correlation of

1. genetic predisposition and the Apigen study led to the conclusion of immune system quality in humans, the similarity of human patterns found in intestinal system was found to cause a kind of immune system without any effects. For instance, bacterium infection, tumour development, intestinal cell damage, but were extremely similar.

It is meant that this system has no effect on human life span and health. However, on the other hand, some pathogens caused severe type-II Gaucher disease with possible immunity responses. This is why this potentially relevant book by Shinya Shinkai â€“ resulting into Cell and Tissue Research â€“ is relevant for people with gut disorder.

In this research, dissimilarity between immune systems in different species was showed to be defective producing intestinal bacterial infection with fewer human immune system. Perhaps it may say that the reason for human life span is insufficient immune system. A program of organ transplants has been discovered to support survival of pancreatic ailment.
